MITRE Techniques

Tactic

Discovery

Technique

System Owner/User Discovery

Adversaries may attempt to identify the primary user, currently logged in user, set of users that commonly uses a system, or whether a user is actively using the system. They may do this, for example, by retrieving account usernames or by using [OS Credential Dumping](https://attack.mitre.org/techniques/T1003). The information may be collected in a number of different ways using other Discovery techniques, because user and username details are prevalent throughout a system and include running process ownership, file/directory ownership, session information, and system logs. Adversaries may use the information from [System Owner/User Discovery](https://attack.mitre.org/techniques/T1033) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Tactic

Defense Evasion

Technique

Access Token Manipulation

Adversaries may modify access tokens to operate under a different user or system security context to perform actions and bypass access controls. Windows uses access tokens to determine the ownership of a running process. A user can manipulate access tokens to make a running process appear as though it is the child of a different process or belongs to someone other than the user that started the process. When this occurs, the process also takes on the security context associated with the new token.

Verdict

MITRE Techniques

Tactic

Defense Evasion

Technique

Process Injection

Adversaries may inject code into processes in order to evade process-based defenses as well as possibly elevate privileges. Process injection is a method of executing arbitrary code in the address space of a separate live process. Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via process injection may also evade detection from security products since the execution is masked under a legitimate process.

Verdict

HIGH RISK

Found API reference SetNamedSecurityInfoW@ADVAPI32.dll

Origin

Extracted File

Found API reference SetNamedSecurityInfoW@ADVAPI32.dll

MITRE Techniques

Tactic	Technique
Defense Evasion	Windows File and Directory Permissions Modification
Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.	

 Executable section has an unusual entropy

Defense Evasion: Software Packing

Verdict

LOW RISK

Origin

Extracted File

.reloc has an unusual entropy 0.633756458759

MITRE Techniques

Tactic	Technique
Defense Evasion	Software Packing

Adversaries may perform software packing or virtual machine software protection to conceal their code. Software packing is a method of compressing or encrypting an executable. Packing an executable changes the file signature in an attempt to avoid signature-based detection. Most decompression techniques decompress the executable code in memory. Virtual machine software protection translates an executable's original code into a special format that only a special virtual machine can run. A virtual machine is then called to run this code.

 Found a living off the land (LotL) string artifact

Defense Evasion: Rundll32

Verdict

LOW RISK

Tags

shell32.dll

Origin

Extracted File

Found string artifact shell32.dll (Execute)

Origin

Input File

Found string artifact shell32.dll (Execute)

MITRE Techniques

Tactic	Technique
Defense Evasion	Rundll32

Adversaries may abuse rundll32.exe to proxy execution of malicious code. Using rundll32.exe, vice executing directly (i.e. [Shared Modules](https://attack.mitre.org/techniques/T1129)), may avoid triggering security tools that may not monitor execution of the rundll32.exe process because of allowlists or false positives from normal operations. Rundll32.exe is commonly associated with executing DLL payloads (ex: <code>rundll32.exe {DLLname, DLLfunction}</code>).
